**Optimal Timing of Laparoscopic Cholecystectomy for Moderate Acute Cholecystitis: A Cohort Study**

1Department Hepatobiliary and Pancreatic Surgery, Affiliated Hospital of Zunyi Medical University, China
2Department of Biochemistry and Molecular Biology, Zunyi Medical University, China

**Abstract**

**Background:** Early Laparoscopic Cholecystectomy (ELC) is superior to Delayed Laparoscopic Cholecystectomy (DLC) for Moderate Acute Cholecystitis (MAC) as defined by Tokyo Guidelines 2013 (TG13) [4] have defined a severity grading system, being used unchanged as the TG18 diagnostic criteria [5], which have testified well regarded as a factor predicting vital prognosis [6]. A long-standing dogma has stipulated that patients with Moderate Acute Cholecystitis (MAC) should not undergo Early LC (ELC) as severe local inflammation makes LC potentially more dangerous. However, with advances in laparoscopic equipment and technology, offering ELC for patients with MAC was reported, and randomized controlled trials [7] has shown it is safe and with similar conversion rate and perioperative complications, shorter total hospital stay and duration of antibiotic therapy compared with Delayed Laparoscopic Cholecystectomy (DLC). This consequence was endorsed in Tokyo Guidelines 2018 (TG18) and ELC should be undergone offering ELC for patients with MAC who can tolerate surgery with over 7 days of admission. In addition, rational and appropriate use of antibiotics should be underscored.

**Keywords:** Moderate acute cholecystitis; Early vs. delayed; Laparoscopic cholecystectomy

**Introduction**

Acute Cholecystitis (AC) is a common acute abdominal disorder and can be fatal if not appropriately treated in time [1]. Laparoscopic Cholecystectomy (LC) is considered a golden standard treatment for AC [2,3]. Tokyo Guidelines 2013 (TG13) [4] have defined a severity grading system, being used unchanged as the TG18 diagnostic criteria [5], which have testified well regarded as a factor predicting vital prognosis [6]. A long-standing dogma has stipulated that patients with Moderate Acute Cholecystitis (MAC) should not undergo Early LC (ELC) as severe local inflammation makes LC potentially more dangerous. However, with advances in laparoscopic equipment and technology, offering ELC for patients with MAC was reported, and randomized controlled trials [7] has shown it is safe and with similar conversion rate and perioperative complications, shorter total hospital stay and duration of antibiotic therapy compared with Delayed Laparoscopic Cholecystectomy (DLC). This consequence was endorsed in Tokyo Guidelines 2018 (TG18) and ELC should be undergone offering ELC for patients with MAC who can tolerate surgery with over 7 days of admission because data remain weak on the specific management of MAC beyond 1 week.

Therefore, the purpose of this study was to evaluate the outcomes of ELC in patients with delayed management.

**Patients and Methods**

We selected a total of 157 patients, associated with biliary stone, were diagnosed with MAC...
according to the TG18 [5] at the Affiliated Hospital of Zunyi Medical University between November 2016 and October 2019. Inclusion criteria were as follows: (1) patients with MAC according to the TG18; (2) the surgeons who performed the LC were professors or associate professors. Patients who were diagnosed with cholangitis, biliary tract tumor, acute pancreatitis or pregnancy were excluded. MAC was diagnosed according to the TG18 with the presence of any one of the following conditions: (1) elevated white blood cell count (>18 × 10^9/L); (2) palpable tender mass in the right upper abdominal quadrant; (3) duration of complaints >72 h; and (4) marked local inflammation (gangrenous cholecystitis, pericholecystic abscess, hepatic abscess, biliary peritonitis, emphysematous cholecystitis). The included patients were classified into three groups according to the time from admission to surgery: Group 1 (G1) within the first 7 days, group 2 (G2) beyond 7 days, group 3 (G3) at least 6 weeks after conservative treatments. Patients diagnosed with MAC were treated with empirical intravenous antibiotic therapy according to the guidelines [3,8]: Cephalosporin or Fluoroquinolone was used.

Our center has advanced laparoscopic equipment and mature laparoscopic technology. All operations used the 3-ports technique, and the 4-ports technique was used if the operation was difficult. For those with gallbladder edema and high tension, puncture and extraction of fluid at the bottom of the gallbladder for decompression and blunt separation of the gallbladder Calot triangle were performed. If there was more exudation in the abdominal cavity, a peritoneal drainage tube was placed near the Winslow hole.

Patient characteristics collected include age, sex, laboratory findings, abdominal ultrasound results, cardiorespiratory co-morbidities, American Society of Anesthesiologists (ASA) score and previous abdominal surgery. Data of surgery include operative time, conversion rate, perioperative complications (bile duct injury, pneumonia, peritonitis, postoperative abdominal bleeding, and incision infection). Total Length of Stay (TLOS), Total Duration of Antibiotic Therapy (TDAT), Total Hospital Costs (THC), Drainage Tube Removal Time (DTRT), Postoperative Duration of Antibiotic Therapy (PDAT), Postoperative Length of Stay (PLOS) was collected and analyzed. This study was approved by the Research Ethics Board from our centre.

### Statistical analysis
All statistical analyses were performed using SPSS 18.0. Normal continuous variables were expressed as mean (Standard Deviation: SD), and compared using the Student’s t test or Bonferroni test. Non-normal continuous variables were expressed as median (Interquartile Range: IQR), and compared using the Mann-Whitney U test or Kruskal-Wallis H test. Categorical variables are shown as frequencies and percentages, and were compared using the Chi-square test or Fisher’s exact test. Multivariable logistic regression analysis and Receiver Operating Characteristic (ROC) curves was performed to determine independent predictors of outcomes. A P value <0.05 was considered significant.

### Results
Between November 2016 and October 2019, 157 patients were diagnosed with MAC, included 85 males and 72 females, ranging in age from 18 to 82 years. Median white blood cell count was 13 × 10^9/L. All cases were thickening of the gallbladder wall on abdominal ultrasound, associated with biliary stone, 55 in G1, 43 in G2, and 59 in G3 (Figure 1).

Compared with G1 and G3, G2 patients were older (G1 47 ± 12 vs. G2 55 ± 14 vs. G3 49 ± 13, P=0.005) and a greater number of hypertension (G1 10.9% vs. G2 30.2% vs. G3 11.9%, P=0.018), which may be the reason why it took longer to evaluate surgical tolerance before surgery. However, there was no statistical difference in the American Society of Anesthesiologists (ASA) score among the three groups (P=1.000) (Table 1).

Regarding surgery data, three patients in G3 were diagnosed with secondary choledocholithiasis received ERCP+LC after re-admission, the operative time was only calculated for the LC. And there was a significant difference in the operative time among the three groups (92 vs. 110 vs. 76 min, P<0.001), G2 had longer operative time than G1 and G3. In G1, 2 patients were converted to open surgery. After surgery, 2 patients had pneumonia, and 1 patient had an incision infection. In G2, 5 patients were converted to laparotomy. After surgery, 2 patients...
Cijun Peng, et al., had peritonitis, 1 patient had pneumonia, and 1 patient had an incision infection. In G3, 3 cases were converted to laparotomy. After surgery, 1 case had pneumonia, 1 case had postoperative abdominal bleeding, 1 case had peritonitis, and 2 cases had an incision infection.

Conversion rate and perioperative complications were (3.6% in G1 vs 11.6% in G2 vs 6.8% in G3, P=0.305) and (5.5% in G1 vs 9.3% in G2 vs 8.5% in G3, P=0.804), respectively. No bile duct or intestinal tract injury was found in the three groups. TDAT, TLOS and THC in G3 involved admission and re-admission parameters. In this study, compared with G2 and G3, G1 had shorter TDAT (7 vs. 11 vs. 9d, P=0.001) and TLOS (8 vs. 14 vs. 15d, P<0.001), lower THC (14654 vs. 20431 vs. 20801¥, P<0.001). G3 had shorter Postoperative Length of Stay (PLOS) (4 vs. 7 vs. 6d, P=0.001), Postoperative Duration of Antibiotic Therapy (PDAT) (3 vs. 3 vs. 2d, P<0.001) and Drainage Tube Removal Time (DTRT) (2 vs. 2 vs. 2d, P=0.002) than G1 and G3 (Table 2).

According to the TG18, there was no difference in PLOS between ELC and DLC. Hence, we analyzed the factors associated with prolonged PLOS and found that age (OR=1.043, 95% CI: 1.003 to 1.084, P=0.034), DTRT (OR=2.838, 95% CI: 1.540 to 5.231, P=0.001) and PDAT (OR=2.953, 95% CI: 1.944 to 4.486, P<0.001) were independent factors for prolonged PLOS (Table 3). Age, DTRT and PDAT had an area under the ROC curve (0.594, P=0.041; 0.826, P<0.001; 0.906, P<0.001; respectively) (Figure 2).

**Discussion**

On the basis of anatomo-pathological observation [9]: Cholecystitis symptoms of more than 72 h results in the development of necrotizing and suppurative cholecystitis making surgery more difficult. According to the TG18 diagnostic criteria, however, those patients are part of MAC. Meanwhile, existing trial have shown ELC to be superior than DLC although necrotizing and suppurative cholecystitis present [7,10]. Nonetheless, the criteria for performing ELC to MAC patients with relatively controversial in current literature.

The TG18 have updated there standpoints and recommendations

---

**Table 1: Patient Characteristics.**

|                      | G 1 (n=55) | G 2 (n=43) | G 3 (n=59) | P  
|----------------------|------------|------------|------------|------
| Sex, n (%)           |            |            |            |

DTRT: Drainage Tube Removal Time; PDAT: Postoperative Duration of Antibiotic Therapy; PLOS: Postoperative Length of Stay; TDAT: Total Duration of Antibiotic Therapy; TLOS: Total Length of Stay; THC: Total Hospital Costs
that ELC should be undertaken within 3 days or 7 days of admission for patients with MAC who can tolerate surgery. However, we found that some patients with MAC required a long time to complete tests and evaluation of surgical tolerance after admission, or surgery is considered until conservative treatment fails. Data remain weak on the specific management of those patients. Therefore, we aimed to compare the outcome among G1 (surgery from admission within the first 7 days), G2 (more than 7 days), and G3 (DLC at least 6 weeks after antibiotic treatment), and we found providing ELC for patients with hospitalized beyond 7 days was safe.

There was no statistically significant difference in conversion rate between the three groups, which confirmed that ELC effectively removed suppurative gallbladder. Converting to open laparotomy is associated with significant disadvantages such as increased surgical trauma and hospital costs [11], although it has no effect on the rate of local postoperative complications [12,13]. Several studies have demonstrated AC is closely associated with the conversion rate [14,15], as well as severity grade was an independent predictor of conversion to open surgery [16]. With the aggravation of gallbladder inflammation, theoretically, the risk of conversion is increased. However, we considered that the conversion rate was similar between ELC and DLC groups in terms of PLOS [7,27], it is estimated that offering ELC which have shown no significant difference between ELC and DLC groups in terms of PLOS [7,27], it is estimated that offering ELC should be performed within 3 days or 7 days of admission for patients with MAC who can tolerate surgery.

A reduction in TLOS and its resultant improvement in THC effectiveness remains a major aspect in supporting the use of ELC over DLC. Studies have demonstrated that the THC in the ELC group are lower than those in the DLC group [25,26]. While THC was higher in G2, this was an expected result as those patients had longer preoperative length of hospital stay and PLOS. And PLOS was longer in G1 and G2, seemingly different from previous studies offering ELC which have shown no significant difference between ELC and DLC groups in terms of PLOS [7,27], it is estimated that patients underwent ELC with longer PDAT which with the intent to reduce infectious complications. Antimicrobial therapy is deemed therapeutic for MAC, and antimicrobial therapy may be required until the gallbladder is removed. However, the recommended duration of antimicrobial therapy for MAC in the TG13 is no more than 7 days.

In recent years, the proportion of secondary choledocholithiasis is increasing in China, and the incidence of secondary choledocholithiasis can be up to 10% to 15% in surgically-treated patients [21,22]. In contrast to choledocholithiasis, most cases of secondary choledocholithiasis do not have symptoms and the diagnosis is often missed [23]. Moreover, if stones obstruct the common bile duct and bacteria ascend the biliary tree and infect the sterile bile, acute cholangitis will occur [24]. This is life-threatening in patients with choledocholithiasis secondary to calculous cholecystitis who refuse surgery after conservative treatment. In our study, 3 patients in the DLC group were diagnosed with secondary choledocholithiasis after re-admission and ERCP followed by LC was performed. As a result, providing ELC for MAC has a lower risk in advanced center, even if patients are hospitalized for more than a week the conversion rate and BDI did not significantly increased.

In patients with LC-associated BDI transferred to advanced center, even if patients are hospitalized for more than a week the conversion rate and BDI did not significantly increased. A retrospective review based on the Nationwide Inpatient Sample analyzed 95,523 patients with AC who underwent LC who have shown prolonged hospitalization before surgery the incidence of BDI did not increase [20], which is consistent with this reports. Because none of the patients with subsequent BDI after LC. We found that most patients with LC-associated BDI were referred from junior hospitals to our center, there are isolated and backward areas in China on the one hand lagged in offering surgeries with laparoscopic skills, which led more patients with LC-associated BDI transferred to advanced center. Therefore, we deem providing ELC for MAC has a lower risk in advanced center, even if patients are hospitalized for more than a week the conversion rate and BDI did not significantly increased.

days after cholecystectomy [8], which is disagreed with the TG18 that postoperative antibiotic therapy is not recommended unless bacteremia with Gram-positive bacteria is present [1]. We prolonged PDAT in the most cases according to the TG18, although we strictly followed the anti-infection criteria, which may be the reason why PLOS is higher in ELC groups. In addition, several studies have shown that prolonged antibiotic therapy after LC is not beneficial in reducing surgical site infection, and which also can cause nausea, allergic reactions and digestive complaints [28, 29]. Nevertheless, increasing incidence of multi-drug resistance caused by overuse of antibiotics has become a major threat to global public health; this phenomenon is particularly serious in China. Thus, reducing unnecessary antibiotic therapy such as PDAT is an important countermeasure to avoid infection by multi-drug resistance bacteria. Rational and appropriate use of antibiotics is also likely to reduce not only PLOS and THC, but antibiotic adverse reactions.

Our study had some limitations. Firstly, surgeons’ preference affects the timing of surgery; therefore, selection bias could not be fully excluded, and the benefits and harms of ELC and DLC may have been overestimated. Secondly, the popularity of LC results in patients not being confined to a single center for treatment, consequently, this study had a small sample size.

Conclusion

ELC is effective and safe in patients with MAC who can tolerate surgery with over 7 days of admission. We agree with the recommendation of the TG18 that LC should be performed by experienced surgeons cases by severe local inflammation of gallbladder. Finally, antimicrobial management should be underscored and prudent antimicrobial usage implemented.
